Abstract:
Background Involvement of the ovary by malignant lymphoma is a well known late manifestation of disseminated nodal disease. Primary ovarian lymphoma is a rare entity. Case History We report an autopsy case of primary ovarian non Hodgkin's lymphoma with bilateral involvement. A 33 year old woman was admitted with signs and symptoms suggestive of an ovarian cancer. Computed tomography revealed two abdominal masses measuring 10cm in diameter, without the enlargement of pelvic lymph nodes. Diagnosis of malignant lymphoma was made on histopathology. Tumour was classified as a diffuse large B cell lymphoma with the help of immunohistochemistry. Absence of disease in blood and bone marrow, absence of lymphadenopathy favours the diagnosis of primary lymphoma.

Keywords: Primary Lymphoma, Ovary

Introduction:
The occurrence of bilateral primary ovarian lymphoma is quite rare and accounts for about 0.5% of Non Hodgkin's lymphomas and 1.5% of all ovarian neoplasms with diffuse large B cell lymphoma being the commonest type.

Case Report:
A 33 years old female was admitted in our hospital with pain and distension of abdomen, pedal oedema, and breathlessness since seven days. Physical examination revealed an abdominopelvic mass of size 10x6 cm. CT abdomen showed two ovarian masses with no evidence of abdominal lymphadenopathy. Her haematological profile was within normal limits. Laparotomy was done and showed bilateral ovarian enlargement total abdominal hysterectomy was done. There was no adhesions and gross infiltration noted. Specimens were subjected to histopathological examination and differential diagnosis of dysgerminoma and Non Hodgkin's ovarian lymphoma was made.

Histopathology:
Gross: Uterus with bilateral adnexa measured 15x8x5cm. Left ovary measured 9x5x3cm and right ovary measured 6x4x3cm. External surfaces of both ovaries were nodular, gray white and cut surface showed diffuse, homogenous, fleshy, gray white to tan coloured mass replacing the ovarian tissue with few areas of haemorrhages. Both fallopian tubes showed diffuse thickening of the wall. Uterus and cervix were grossly unremarkable.

Microscopy:
Sections from bilateral ovarian masses showed a tumour with diffuse solid pattern composed of monotonous large round cells with round to oval nucleus, having coarse chromatin, 1-2 prominent nucleoli and scanty cytoplasm. So diagnosis of Non Hodgkin's lymphoma was made supported by Immunohistochemistry which showed positivity of tumour cells for B lineage markers (CD20) and negativity for T lineage markers. Sections from bilateral fallopian tubes, uterus and cervix were free from tumour invasion.
Malignant lymphoma, which has a 5 year survival rate of only 25%. The ovarian involvement in malignant lymphoma may be primary or secondary. Whether primary or secondary, ovarian lymphomas may have varied presentation, most of them being discovered incidentally during the work up for pelvic or abdominal complaints. The distinction is important because primary extra nodal lymphoma runs a less aggressive course with 5 year survival rate of 80% as compared to secondary malignant lymphoma, which has a 5 year survival rate of only 33%. As suggested by Fox et al, diagnostic criteria for primary ovarian lymphoma are a) disease confined to ovary, b) absence of disease in blood and bone marrow; c) the extra ovarian deposits if any should appear at least after few months. But diagnosis of primary lymphoma may still be considered if the spread has occurred to the adjacent lymph nodes or to the immediately adjacent structures. In our case there was no obvious lymphadenopathy and blood, bone marrow, spleen or hepatic involvement. Adjacent structures like fallopian tubes, parametrium and broad ligament were not involved. All these findings favour the diagnosis of primary ovarian lymphoma. Lymphomas of the ovary may occur at any age, but mostly women in their 40s are affected. Patients presenting with rapid onset abdominal pain and distension had worse prognosis. Our patient also presented with rapid onset of abdominal pain and distension which proved fatal. Malignant lymphoma of the ovary may be confused with other primary ovarian tumours like dysgerminoma, granulocytic sarcoma, granulosa cell tumor, undifferentiated carcinoma and metastatic breast carcinoma, of which dysgerminoma is the commonest which mimics lymphoma both microscopically and macroscopically. Only 10% of dysgerminomas are bilateral in contrast to 50% of the lymphomas. Microscopically the cells of dysgerminoma are uniform with PAS+ve, diastase sensitive, clear cytoplasm whereas in lymphoma cytoplasm is scanty and PAS negative.

Granulocytic sarcoma on routine stains is often composed of cells with more finely dispersed chromatin and abundant deeply eosinophilic cytoplasm compared to lymphoma cells which have nuclei of same size with coarse chromatin and scanty cytoplasm. The findings of granulated myelocytes are diagnostic of granulocytic sarcoma. The single file arrangement of lymphoma cells may simulate metastatic carcinoma particularly one of breast origin. However in such cases history of primary mammary carcinoma is present. Morphologically cells in breast carcinoma have irregular margins, they retain their intercellular attachments, form cohesive sheets and at times produce small amount of intracytoplasmic mucin. Granulosa cell tumours are distinguished from lymphoma by grooved nuclei, formation of Call-Exner bodies and tendency to merge with thecomatous areas. At laparotomy extra ovarian involvement is found in 2/3rd of patients with lymphoma as seen in our case. Diffuse infiltration of the adjacent fallopian tubes and broad ligament found in our case is more commonly seen in lymphomas than in other primary and metastatic tumours of the ovaries. Immunohistochemistry in our case showed positivity of tumour cells for B lineage markers (CD20 and CD79a) and negativity for T lineage markers (CD3 and CD138). It also showed only 30% MIB1 activity which is lower as compared to high proliferative activity in case of Burkitt's lymphoma. On the basis of microscopic findings supported by immunohistochemistry, diagnosis of primary Non Hodgkin's lymphoma of the ovary was made.

**Conclusion:**

Primary Non Hodgkin’s ovarian lymphoma is rare. It needs to be differentiated from other ovarian malignancies, as its management differs from other primary and metastatic ovarian tumours.
